Interview Assessment - The Task

Goal

A small price lookup service. Given a product SKU, it returns a price from an ERP-like source instead of a hardcoded value.

Minimal code to write (keep it small)

- A backend endpoint (for example GET /products/{sku}/price) that calls an ERP client interface, validates the SKU, and maps the result to a response DTO.
- An ERP client interface with a simulated implementation (a fake or in-memory stub that returns a price, currency and last-updated timestamp, and can be told to time out or fail). Include the stub in the repo.
- A small test suite covering at least: a found SKU, an unknown SKU, and an ERP timeout or failure.

Written only (no code needed)

The frontend (SKU input, price display, loading and error states) and the middleware (BFF route or server action). Describe how they would call the endpoint, what they'd handle in the UI, and how errors map from the backend.

Architecture sketch

Markdown, hand-drawn diagram, you name it. Important is that it is accessible by our party.

Time budget

The task should take 1 to 2 days. Remember: we don't expect production polish.

Submission

A GitHub public repo containing the code, tests, README, and any sketch.
